$$\triangleright |z_1 z_2| = |z_1| |z_2|$$

$$\qquad \left| \frac{z_1}{z_2} \right| = \frac{|z_1|}{|z_2|}$$

$$\triangleright |z_1 + z_2| \neq |z_1| + |z_2|$$

Complex variable

$$s = \sigma + j\omega$$

$$Re(s) = \sigma$$

$$Im(s) = \omega$$
 Both real quantities. At leat one is a variable

Complex function

$$F(s) = F_{x} + jF_{y} \qquad \overline{F}(s) = F_{x} - jF_{y}$$

$$Re(F(s)) = F_{x}$$

$$Im(F(s)) = F_{y}$$

$$Both real quantities$$

$$\theta = \tan^{-1}\left(\frac{F_{y}}{F_{x}}\right)$$

Typically, such functions have the form:

$$F(s) = K \frac{a_m s^m + a_{m-1} s^{m-1} + \dots + a_o}{b_n s^n + b_{n-1} s^{n-1} + \dots + b_o} = K \frac{(s + z_1)(s + z_2) \dots (s + z_m)}{(s + p_1)(s + p_2) \dots (s + p_n)}$$

$$F(s) = 0 \to s = -z_1, -z_2, \dots, -z_m \text{ (zeros). Some may be at infinity } (\infty)$$

$$F(s) = \infty \to s = -p_1, -p_2, \dots, -p_n \text{ (poles, simple)}$$

$$F(s) = \infty : (s + n)^k \to s = -n \text{ (multiple / repeated note)}$$

 $F(s) = \infty$; $(s+p)^k \rightarrow s = -p$ (multiple/repeated pole)

Example 1

Find the zeros and poles of the complex functions:

(a)
$$F(s) = K \frac{(s+2)(s+10)}{s(s+1)(s+5)(s+15)^2}$$

(b)
$$F(s) = \frac{7(s-4)}{s^2 (s^2 - 6s - 27)}$$

(c)
$$F(s) = \frac{1}{(s^2 + 1)(s^2 + 4s + 20)}$$

- The <u>Laplace transform</u> is an operational method that can be used advantageously in solving LTI ODEs.
- Another advantage is that it converts linear differential equations in t domain into algebraic equations in s domain.
- In solving the differential equation, the initial conditions are automatically taken care of, and both the particular solution and the complementary solution can be obtained simultaneously.
- The Laplace transform $\mathcal{L}[f(t)]$ of a function f(t), real function of time, is defined as follows:

$$\mathcal{L}[f(t)] = \lim_{T \to \infty} \left[\int_0^T f(t)e^{-st} dt \right]$$

$$\mathcal{L}[f(t)] = \int_0^\infty f(t)e^{-st}dt = F(s)$$

$$f(t) = \begin{cases} ?, & t \ge 0 \\ 0, & t < 0 \end{cases}$$

s: complex variable

 \mathcal{L} : Laplace transform operator

$$f(t) = \mathcal{L}^{-1}[F(s)]$$

 \mathcal{L}^{-1} : inverse Laplace transform operator

- For some relatively simple functions either the Laplace transform does not exist (such as for e^{t^2} and 1/t), or it cannot be represented as an algebraic expression.
- The Linearity Property

If $\mathcal{L}[f_1(t)]$ and $\mathcal{L}[f_2(t)]$ exist, then

$$\mathcal{L}[f_1(t) + f_2(t)] = \mathcal{L}[f_1(t)] + \mathcal{L}[f_2(t)]$$

Also,

$$\mathcal{L}^{-1}[F_1(s) + F_2(s)] = \mathcal{L}^{-1}[f_1(t)] + \mathcal{L}^{-1}[f_2(t)]$$

- Properties of Laplace Transforms
 - Comments on the lower limit of the Laplace integral
 - In some cases, f(t) possesses a discontinuity in the function at t = 0.
 - This phenomenon occurs in models having impulse inputs and in models containing derivatives of a discontinuous input, such as a step function.
 - Then the lower limit of the Laplace integral must be clearly specified as to whether it is 0 or 0 +; The Laplace transforms of f(t) will differ for these two lower limits.

$$\mathcal{L}_{+}[f(t)] \neq \mathcal{L}_{-}[f(t)], \quad \text{since } \int_{0-}^{0+} f(t)e^{-st}dt \neq 0$$

 If such a distinction of the lower limit of the Laplace integral is necessary, we use the notations

$$\mathcal{L}_{+}[f(t)] = \int_{0+}^{\infty} f(t)e^{-st}dt \qquad \text{and} \qquad \mathcal{L}_{-}[f(t)] = \int_{0-}^{\infty} f(t)e^{-st}dt$$
$$= \int_{0-}^{0+} f(t)e^{-st}dt + \mathcal{L}_{+}[f(t)]$$

Properties of Laplace Transforms

Differentiation theorem

• To solve differentiation equations, we will need to obtain the transforms of derivatives.

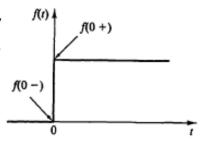

$$\mathcal{L}\left[\frac{d}{dt}f(t)\right] = \int_0^\infty \frac{df(t)}{dt} e^{-st} dt$$

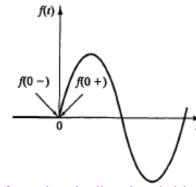

• For a given function f(t), the values of f(0+) and f(0-) may be the same or different. f(t) may have a discontinuity at t=0, and in such a case, df(t)/dt will involve an impulse function at t=f(0-) 0; $f(0+) \neq f(0-)$.

$$\mathcal{L}_{\pm} \left[\frac{d^2}{dt^2} f(t) \right] = s^2 F(s) - s f(0 \pm) - \dot{f}(0 \pm)$$

$$\mathcal{L}\left[\frac{d}{dt}f(t)\right] = sF(s) - f(0)$$

$$\mathcal{L}_{\pm}\left[\frac{d}{dt}f(t)\right] = sF(s) - f(0\pm)$$

Step function and sine function indicating initial values at t = 0 – and t = 0 +

$$\mathcal{L}_{\pm} \left[\frac{d^n}{dt^n} f(t) \right] = s^n F(s) - s^{n-1} f(0 \pm) - s^{n-2} \dot{f}(0 \pm) - \dots - f^{n-1}(0 \pm)$$

(b)
$$\ddot{x} - 4\dot{x} + x = t$$
, $x(0) = 1$, $\dot{x}(0) = 3$
